### Abstract

Novel tungstate  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}:\text{xEu}^{3+}$  ( $x = 0, 0.03, 0.06, 0.09, 0.12, 0.15, 0.18, 0.21$ ) red phosphors were prepared by solid state method at  $1150^\circ\text{C}$  by using  $\text{SrCO}_3$ ,  $\text{La}_2\text{O}_3$ ,  $\text{WO}_3$  and  $\text{Eu}_2\text{O}_3$  as raw materials. The powders were agglomerated with particles having mostly spheroidal morphology, mean particle size  $D_{50} = 12.8\ \mu\text{m}$  and narrow particle size distribution. With the increase of doping amount  $x$ , there is no significant difference in the diffraction peak position of the phosphor, but the cell volume of  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  slowly decreases. The relative strength of diffraction peaks decreases gradually and the half-peak width widens gradually, indicating that the inclusion of  $\text{Eu}^{3+}$  ions affects the crystallization of the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  matrix. Excitation and emission spectra of the prepared samples were obtained. The optimal doping content has the  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}:\text{0.15Eu}^{3+}$  phosphor and is characterised with the colour coordinate of (0.652, 0.348), which is closer to the red standard colour (0.67, 0.33) than the near-ultraviolet red phosphor  $\text{Y}_2\text{O}_2\text{S}:\text{Eu}^{3+}$  (0.622, 0.351) used for commercial LED.

**Keywords:** Eu-doped  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$ , phosphor, powder, structure, luminescence properties

### I. Introduction

Tungstate is one of the most classic inorganic luminescent materials. As early as 1896, Pupin discovered that  $\text{CaWO}_4$  could be applied for X-ray luminescence, and it was first used as an X-ray luminescence material in 1906 [1]. In recent years, the application of tungstate activated by rare earth ion  $\text{Eu}^{3+}$  in white LED is also significant [2–4]. However, there are no reports on the preparation of phosphors with rare earth ion doping or transition metal ion doping of  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$ . Therefore,  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}:\text{Eu}^{3+}$  phosphor was studied in this paper.

LED is a solid-state light source that has the characteristics of long lifespan, low energy consumption, energy conservation and low-carbon, no ultraviolet radiation and no mercury pollution. At present, it has been widely used in various fields such as indicator lights, displays, lighting, communication, etc. [5–7]. LED is

a new and important light source in the 21<sup>st</sup> century. Among them phosphor conversion (PC) white LED has received much attention. At present, the main problems with white light LEDs are: i) too high costs, especially the cost of high brightness LEDs [8], ii) very low luminous efficiency of LED [9] and iii) lack of high-performance fluorescent powders. Su *et al.* [10] pointed out that the most prominent problem with the white LED scheme combining InGaN blue chip with YAG:Ce yellow fluorescent powder is that the white LED colour rendering index is only 60–70, and it is difficult to exceed 75. Generally, indoor lighting requires a colour rendering index of the light source greater than 80, and the white light scheme combining blue LED and yellow powder mentioned above cannot be achieved separately. The main reason for this result is that the proportion of red light in YAG:Ce fluorescent powder and the intensity are low. In YAG:Ce fluorescent powder, the red light spectral energy only accounts for 8% to 15% of the total spectral energy, which is much lower than

\*Corresponding author: tel: +86 798 8499328  
e-mail: fengguo@jci.edu.cn

the proportion of yellow green light. Therefore, in order to improve the colour rendering index of packaged LED light sources and obtain products with appropriate colour temperature, a certain amount of red fluorescent powder must be added to YAG: Ce fluorescent powder during packaging. Currently, almost all low colour temperature white LED products on the market are manufactured using this method. However, efficient red fluorescent powder has become a bottleneck in the development of white LED [11], and currently, in the scheme of adding RGB fluorescent powder to ultraviolet chips, the efficiency of red, green and blue fluorescent powders has been greatly improved, but the efficiency of red fluorescent powder is the lowest [12]. The development of new red fluorescent powders is a key issue in achieving high-performance light conversion white LED [12,13], which also makes the development of high-efficiency red fluorescent powders for LED a current research hotspot.

The reported fluorescent powder preparation methods include: solid state method [14–16], sol-gel method [17–19], precipitation method [20,21], spray drying method [22,23], ultrasonic spray pyrolysis method [24,25], hydrothermal method [26,27], etc. The wet chemical method used to prepare fluorescent powder might have relatively good powder morphology, and the relative brightness may be similar to that of samples prepared by high-temperature solid state method. In some systems, the relative brightness can even be comparable to that of samples prepared by high-temperature solid state method (in general, the relative brightness of fluorescent powder prepared by wet chemical method is only 70% to 80% of that prepared by high-temperature solid state method. However, the above methods have the drawbacks of low production or high equipment requirements, which are not conducive to the practical application of fluorescent powders with important practical significance. In addition, wet chemical methods inevitably result in loss of raw materials during the preparation process, leading to significant errors in experimental reproducibility. Therefore, in this article we adopted the solid state method to prepare samples.

## II. Experimental

The starting materials  $\text{SrCO}_3$  (Shanghai Aladdin Co. Ltd.),  $\text{La}_2\text{O}_3$  (Shanghai Aladdin Co. Ltd.),  $\text{WO}_3$  (Sinopharm Chemical Reagent Co. Ltd.) and  $\text{Eu}_2\text{O}_3$  (Sinopharm Chemical Reagent Co. Ltd.) were weighted according to the nominal compositions  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}:x\text{Eu}^{3+}$  ( $x = 0, 0.03, 0.06, 0.09, 0.12, 0.15, 0.18, 0.21$ ). Then they were blended in agate mortar and calcined in an alumina crucible at  $1150^\circ\text{C}$  for 2 h in air to complete conventional solid state reactions.

Phase composition of the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}: \text{Eu}^{3+}$  phosphors was identified by recording the powder X-ray diffraction (XRD) patterns using X'pert PRO X-ray diffractometer with  $\text{Cu K}\alpha_1$  radiation ( $\lambda = 1.54056 \text{ \AA}$ ). Microstructure of the samples was observed by field-emission scanning electron microscopy (FE-SEM, SU-

8010, JEOL, Japan). The particle size and distribution of the powders were characterized by laser particle size analyser (Mastersizer 3000, Malvern, UK). Excitation and emission spectra were measured by using Hitachi F-4500 spectrofluorometer equipped with a 60 W Xenon lamp as excitation source. The chromaticity data were taken by using the PMS-50 spectra analysis system. All of the measurements were performed at room temperature.

## III. Results and discussion

### 3.1. Phase composition

Figure 1 shows XRD patterns of the prepared powders with the nominal compositions  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}:x\text{Eu}^{3+}$  where  $x = 0, 0.03, 0.06, 0.09, 0.12, 0.15, 0.18$  and  $0.21$ . It can be seen from Fig. 1 that the diffraction peaks of all samples containing  $\text{Eu}^{3+}$  are identical to those of the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  (PDF card No. 29-1463) in the range of  $10^\circ \leq 2\theta \leq 60^\circ$ . No secondary phase diffraction peaks were detected. It is worth noting that the relative intensity of the XRD peaks becomes lower and the half-peak width gradually becomes wider with the increase of  $\text{Eu}^{3+}$  ions doping under the same preparation and testing conditions. The results indicated that the incorporation of  $\text{Eu}^{3+}$  ions hindered the crystallization of  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$ .

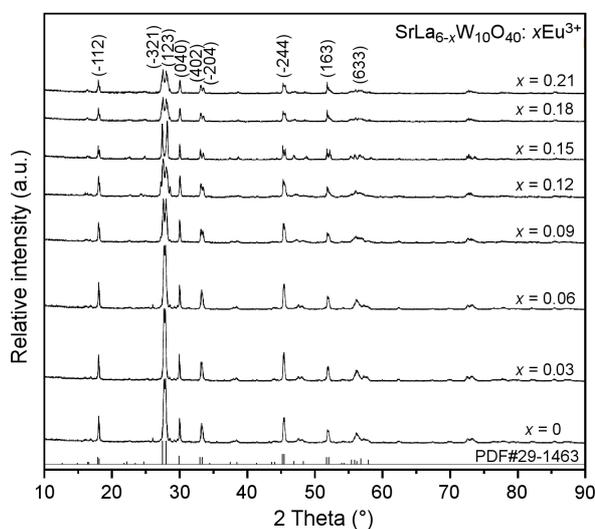

Figure 1. XRD patterns of  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}: x\text{Eu}^{3+}$

In order to facilitate clear comparison, XRD patterns of the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  and  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  samples are shown in Fig. 2. The XRD patterns of both phosphor samples are similar to that of the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  phase (PDF card No. 29-1463) regarding to peak position and relative intensity. No other diffraction peaks of any impurity phase were detected in the XRD patterns. In addition, there is no obvious peak position shift in the XRD patterns of  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  and  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  samples. These results indicated that the addition of  $\text{Eu}^{3+}$  ions did not change the

0.21	12.1882	11.8957	11.8759	1721.81

crystal structure of SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub>, resulting in the formation of single phase material. The cell parameters and cell volume of the SrLa<sub>6-x</sub>W<sub>10</sub>O<sub>40</sub>: xEu<sup>3+</sup> (x = 0, 0.03, 0.06, 0.09, 0.12, 0.15, 0.18, 0.21) samples are given in Table 1. In the investigated compositional range, cell volume of the sample decreases slowly with the increase of Eu<sup>3+</sup> doping amount. This indicates that Eu<sup>3+</sup> ions are incorporated into the SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub> lattice. The reasons why the SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub> crystal structure is not changed with addition of Eu<sup>3+</sup> ions are the valence state of Eu<sup>3+</sup>

and La<sup>3+</sup> ions and similar radius of Eu<sup>3+</sup> and La<sup>2+</sup> ions for the same coordination number [28] (when the coordination number CN = 8, the radii of Eu<sup>3+</sup> and La<sup>3+</sup> ions are 0.107 nm [29] and 0.116 nm [28], respectively). However, it can be concluded that the Eu<sup>3+</sup> doping affects the crystallization of SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub>, since at higher Eu<sup>3+</sup> ion doping the diffraction peak intensity and the half-peak width of each diffraction peak gradually increases.

In order to further investigate the influence of Eu<sup>3+</sup> ion doping on the crystal structure of SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub>, the undoped SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub> sample and the SrLa<sub>5.85</sub>W<sub>10</sub>O<sub>40</sub>: 0.15Eu<sup>3+</sup> with the best luminescence performance were mixed according to mass ratio 1:1 and analysed by XRD (Fig. 3). It can be seen from Fig. 3a that the diffraction peak corresponding to each crystal plane of the powder mixture has a relatively obvious fork peak, showing a small peak next to the main peak. In order to make this fork peak more obvious, the diffraction peak corresponding to the (400) crystal plane (2θ = 29.970°) in the mixed powder is magnified (Fig. 3b). This confirmed that the XRD peak corresponding to the crystal plane (400) is fork peak (Fig. 3b), and the positions of two peaks are 2θ = 30.037° and 30.122°, respectively. This is a manifestation of the influence of doping ions entering the lattice on the matrix lattice. It is worth noting that the relative strength of the fork peak at higher angle 2θ = 30.122° is weaker than that at lower angle 2θ = 30.037°. It corresponds to the gradual weakening of the relative intensity of the XRD peaks with the increase of Eu<sup>3+</sup> ion doping (under the same preparation and test conditions). These phenomena confirm that Eu<sup>3+</sup> ions have doped into the matrix lattice.

### 3.2. Morphology analysis

Figure 4 shows SEM micrographs of the SrLa<sub>5.85</sub>W<sub>10</sub>O<sub>40</sub>: 0.15Eu<sup>3+</sup> phosphor sample heated at 1150°C for 2 h. It can be seen from Fig. 4 that the sample consists of agglomerated particles which are partially sintered during the heat treatment process. The particles do not show obvious consistent shape (some

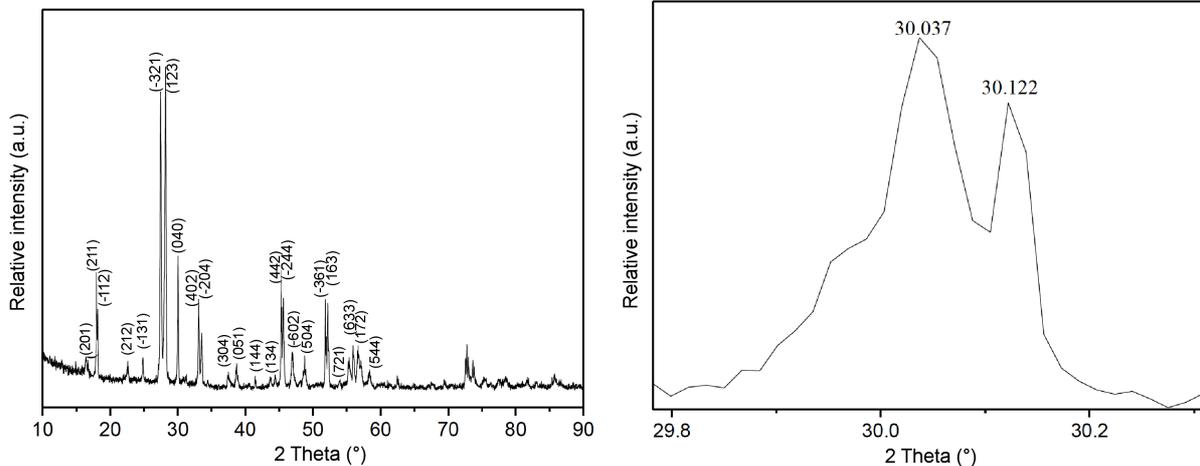

Figure 3. XRD pattern of SrLa<sub>6</sub>W<sub>10</sub>O<sub>40</sub> and SrLa<sub>5.85</sub>W<sub>10</sub>O<sub>40</sub>: 0.15Eu<sup>3+</sup> mixed powder (a) and enlarged XRD pattern (b)

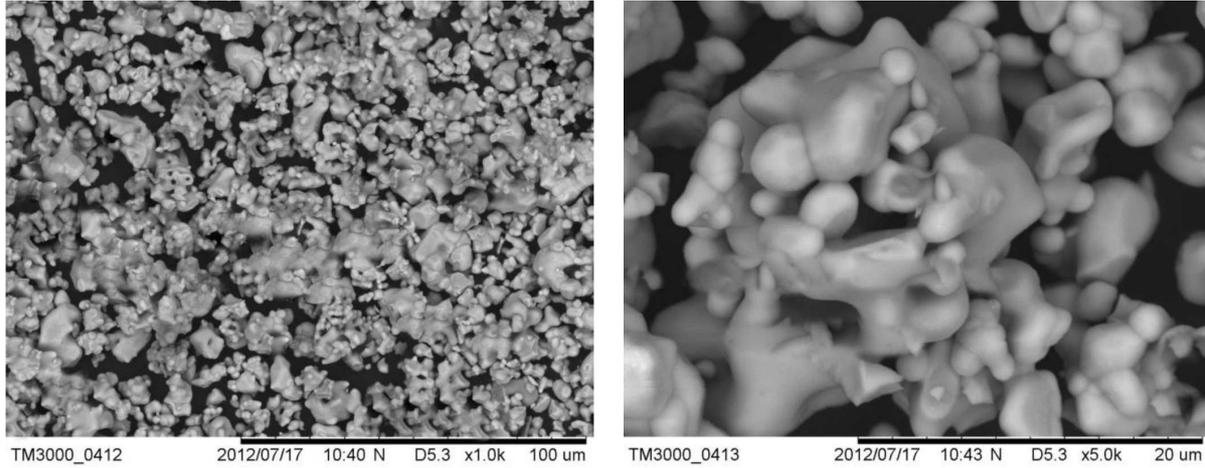

Figure 4. SEM photographs of the  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}:0.15\text{Eu}^{3+}$  phosphor

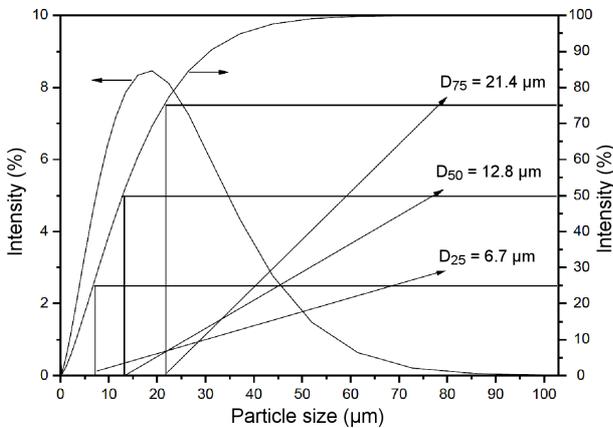

Figure 5. Particle size distribution of  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}:0.15\text{Eu}^{3+}$  phosphor

particles are spherical) and the particle size ranged from one to dozens of  $\mu\text{m}$  with the average particle size of about  $13 \mu\text{m}$ . The grain edges and surfaces are clear, indicating that the sample has good crystallization and good grain development, which corresponds to the XRD results showing high diffraction peak intensity and narrow half-peak width.

Figure 5 shows the laser particle size test results of  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}:0.15\text{Eu}^{3+}$  phosphor. The  $D_{50}$  of the  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}:x\text{Eu}^{3+}$  phosphor sample is  $12.8 \mu\text{m}$  (Fig. 5), which is similar to the average particle size obtained by SEM. The particle size distribution, evaluated by  $(D_{75} - D_{25}) / (D_{25} + D_{75})$ , where  $D_{25} = 6.74 \mu\text{m}$  and  $D_{75} = 21.4 \mu\text{m}$ , is relatively narrow since the corresponding ratio is 0.52.

### 3.3. Optical properties

#### Excitation spectra

Figure 6 shows the excitation spectrum (measured with light having wavelength of  $\lambda_{em} = 610 \text{ nm}$ ) of the  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}:0.15\text{Eu}^{3+}$  phosphor sample, showing an absorption band in the range of 210–280 nm with maximum at 261 nm. This absorption band contains the following three components - ligand-to-metal charge-

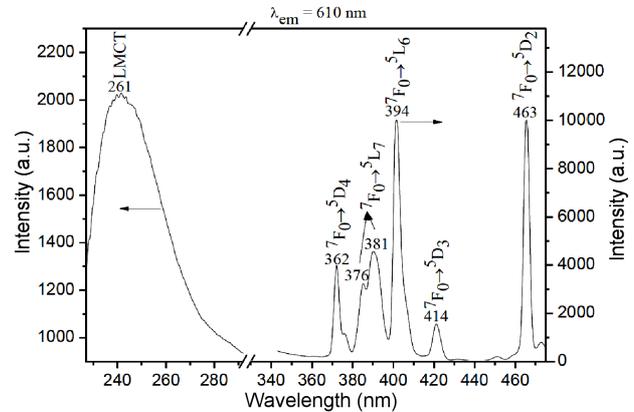

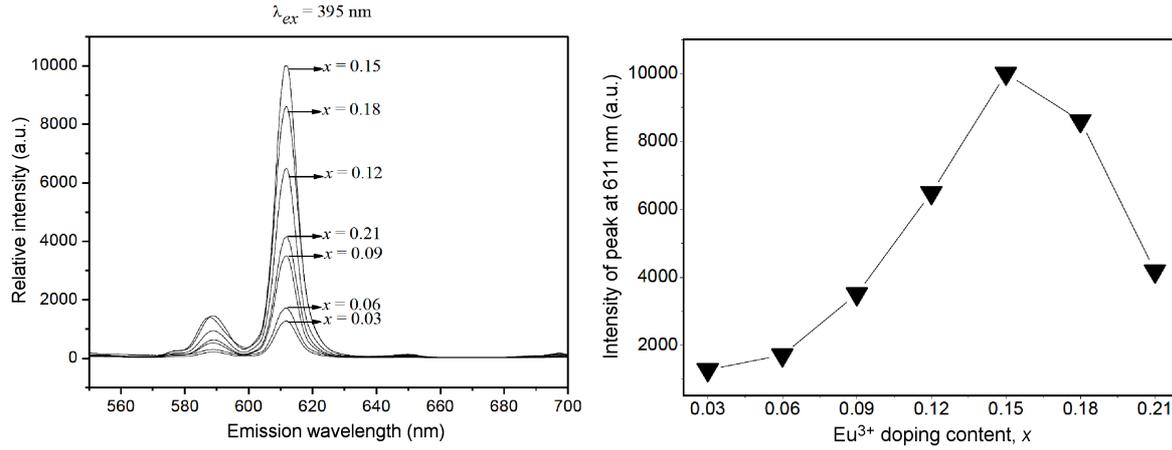

Figure 6. Excitation spectrum of  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}:0.15\text{Eu}^{3+}$  phosphor

transfer (LMCT) formed by electron transfer from: (1)  $\text{O}^{2-}$  to  $\text{Eu}^{3+}$ , (2)  $\text{O}^{2-}$  to  $\text{W}^{6+}$  and (3) from tungstate to  $\text{Eu}^{3+}$  [30]. This also indicates that  $\text{Eu}^{3+}$  ions have been doped into the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  matrix lattice.

The excitation spectra also have 5 peaks at around 362, 376, 381, 394, 414 and 463 nm. The peak at 350 nm belongs to the  $f-f$  (i.e., the intrinsic excitation peak of  $\text{Eu}^{3+}$  ion) excitation peak of  $\text{Eu}^{3+}$ . The two strong peaks are located at 394 and 463 nm, corresponding to the  ${}^7F_0 \rightarrow {}^5L_6$  and  ${}^7F_0 \rightarrow {}^5D_2$  transitions of  $\text{Eu}^{3+}$ , respectively. The excitation peak at 394 nm is strong and matches well with the emission wavelength of the near-ultraviolet region, indicating that the sample is an ideal phosphor for near ultraviolet LED. The excitation peak at 463 nm matches the emission wavelength of the blue region, indicating that the sample is also an ideal phosphor for the blue light LED. In addition, the excitation peak at 362 nm is attributed to the  ${}^7F_0 \rightarrow {}^5D_4$  [31] level transition of  $\text{Eu}^{3+}$  ion, and the excitation peaks at 376 and 381 nm are formed by the  ${}^7F_0 \rightarrow {}^5L_7$  level transition of  $\text{Eu}^{3+}$  ion [32,33]. The excitation peak at 414 nm is caused by the  ${}^7F_0 \rightarrow {}^5D_3$  transition of  $\text{Eu}^{3+}$  ion [34]. In  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  matrix, the splitting of  $\text{Eu}_3^{3+}$  by  ${}^7F_0 \rightarrow {}^5L_7$  level transition indicates that  $\text{Eu}^{3+}$  is in a distorted state in the matrix [35].

**Figure 9. Emission spectra of phosphors with different  $\text{Eu}^{3+}$ -doping contents  $x$  (a) and intensities of the emission peak at 611 nm for different  $\text{Eu}^{3+}$ -doping contents (b)**

fore, the fluorescence intensity decreases with the increase of the concentration of  $\text{Eu}^{3+}$  and the optimal doping amount in the  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}: x\text{Eu}^{3+}$  phosphor is  $x = 0.15$ .

The critical concentration of  $\text{Eu}^{3+}$  in  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  cell ( $\chi_C$ ) was calculated by the formula of critical distance  $R_{\text{Eu-Eu}}$ :

$$R_{\text{Eu-Eu}} = 2 \left( \frac{3V}{4\pi \cdot \chi_C \cdot N} \right)^{1/3} \quad (1)$$

where  $V$  is the volume of the original cell and  $N$  is the number of matrix cations in the original cell. Since the cell volume of the  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  phosphor is  $1.72288 \text{ nm}^3$  (Table 1) and the critical distance of  $\text{Eu}^{3+}$  in the  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  cell is about 2.22 nm, critical quenching concentration was calculated to be 0.025.

#### Colour coordinate

Table 2 lists the colour coordinate values of samples with different doping amounts of  $\text{Eu}^{3+}$  ions. Difference of colour coordinate values for the samples with different  $\text{Eu}^{3+}$  ion doping contents is small, indicating that the sample has good chrominance stability [39]. The colour coordinates of the  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  phosphor are (0.652, 0.348) which is closer to the standard colour coordinate of red (0.67, 0.33) than that of  $\text{Y}_2\text{O}_3\text{S}: \text{Eu}^{3+}$  (0.622, 0.351) [40,41]. This indi-

**Table 2. Chromaticity coordinate values of  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}: x\text{Eu}^{3+}$  phosphors**

Sample	$x$	$y$
$\text{SrLa}_{5.97}\text{W}_{10}\text{O}_{40}: 0.03\text{Eu}^{3+}$	0.651	0.349
$\text{SrLa}_{5.95}\text{W}_{10}\text{O}_{40}: 0.06\text{Eu}^{3+}$	0.651	0.348
$\text{SrLa}_{5.91}\text{W}_{10}\text{O}_{40}: 0.09\text{Eu}^{3+}$	0.652	0.348
$\text{SrLa}_{5.88}\text{W}_{10}\text{O}_{40}: 0.12\text{Eu}^{3+}$	0.652	0.348
$\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$	0.652	0.348
$\text{SrLa}_{5.82}\text{W}_{10}\text{O}_{40}: 0.18\text{Eu}^{3+}$	0.652	0.348
$\text{SrLa}_{5.79}\text{W}_{10}\text{O}_{40}: 0.21\text{Eu}^{3+}$	0.650	0.349

cates that  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  phosphor has very high colour purity. Therefore, the phosphor of tungstate system can be used as the red phosphor in white LED system with three primary colours in near ultraviolet chip. It can also be used as a complementary phosphor to make up for the deficiency of red light components in the commercialized InGaN blue chip plus YAG: Ce yellow phosphor white LED system and improve its colour rendering.

#### IV. Conclusions

Novel tungstate  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}: x\text{Eu}^{3+}$  ( $x = 0, 0.03, 0.06, 0.09, 0.12, 0.15, 0.18, 0.21$ ) red phosphor powders were prepared by solid state method at  $1150^\circ\text{C}$  for 2 h by using  $\text{SrCO}_3$ ,  $\text{La}_2\text{O}_3$ ,  $\text{WO}_3$  and  $\text{Eu}_2\text{O}_3$  as raw materials. The powders were agglomerated with particles having mostly spheroidal morphology, mean particle size  $D_{50} = 12.8 \mu\text{m}$  and narrow particle size distribution. XRD analyses confirmed that  $\text{Eu}^{3+}$  ions were incorporated in the tungstate lattice and there were no diffraction peaks of any impurity phase. With the increase of  $\text{Eu}^{3+}$  doping amount there was no significant difference in the diffraction peak position of the phosphor, but the cell volume of  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  slowly decreased.

The spectral analyses confirmed that the optimal doping amount in the  $\text{SrLa}_{6-x}\text{W}_{10}\text{O}_{40}: x\text{Eu}^{3+}$  phosphor is  $x = 0.15$ . The excitation spectrum of  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  phosphor has an absorption band in the range of 210–340 nm with maximum at 280 nm. The main peak of its emission spectrum is 611 nm, which is the red emission generated by the  $^5D_0 \rightarrow ^7F_2$  level transition of  $\text{Eu}^{3+}$ . Therefore, the obtained tungstate can be used as the red phosphor of white LED system with three primary colours in near ultraviolet chip. The  $\text{SrLa}_{5.85}\text{W}_{10}\text{O}_{40}: 0.15\text{Eu}^{3+}$  powder has excellent luminous intensity and luminous efficiency. The quenching concentration is 0.025 and the critical distance of  $\text{Eu}^{3+}$  in  $\text{SrLa}_6\text{W}_{10}\text{O}_{40}$  matrix is 2.22 nm.
